### ABSTRACT

Switch-mode power supplies usually emit electromagnetic interferences at the switching frequency and its multiple harmonics. We propose a feedback control method improving switch-mode power supplies electromagnetic compatibility (spectral peaks compliance). Inducing chaos in these systems has recently been suggested as a means of reducing these spectral emissions. Indeed, the application of the classical method of chaos anticontrol to these systems leads the output voltage to have an excessive ripple or an undesirable spectrum, whereas these problems are solved with ours. We propose here a converter, able at the same time to achieve low spectral emission and to maintain a small ripple. The design of this controller is based on the property that chaotified nonlinear systems present many independent chaotic attractors of small dimensions. To confirm the efficiency of this method, a comparison with the anticontrol method is included, together with a numerical example clearly showing the effect of this control.

## 1. INTRODUCTION

Power electronic circuits are prone to various types of nonlinear phenomena, like bifurcation and chaos. Among different types of power electronic circuits [1]-[3], dc-dc converters are most widely explored. Bifurcation and chaos, a phenomenon which can naturally occur in switch-mode power supplies has been reported in voltage-mode controlled Buck converters and Boost converters operating in continuous or discontinuous conduction mode. All the reported literatures [2] [3] assume that the input of a dc-dc converter is a regulated dc power supply: this usually is not the case in reality. The converters are mostly fed from a rectified and filtered source; in this case, this dc voltage will contain ripple (the peak to peak input voltage).

Switch-mode power supplies generate electromagnetic interference at the switching frequency and its multiple harmonics. Interference emission creates significant electromagnetic compatibility (EMC) difficulties, especially when high currents or high voltages are switched rapidly. The reduction of spectral emissions can be achieved through various methods that modulate the switching frequency [4]. The work of [5] presents the idea that chaos might be used to improve their EMC by reducing spectral peaks. This advantage is unfortunately counterbalanced by the increase of the peak to peak output voltage [6].

The task of intentionally creating chaos – called anticontrol of chaos – has attracted a lot of attention, becomes a key in such applications where chaos is important and useful. It is well known that chaos can be generated via different approaches [7]-[11], such as feedback techniques or switching methods, to obtain various chaotic attractors from the new chaotic system or circuit. Other techniques to create chaos

are to use a time-delay feedback perturbation on a system parameter or to employ an exogenous time-delay state-feedback input.

The anticontrol method designs a nonlinear feedback controller with an arbitrarily small amplitude [9] [10], thus obtaining chaotic dynamics in the controlled system. The application of this method [6] [10] to switch-mode power supplies reduces the output voltage spectral emissions, but increases the overall magnitude of the output voltage.

After the study of the photovoltaic systems [22][23], the purpose of this article is to introduce a nonlinear feedback controller that maintains a small ripple in the output voltage and also achieves a low spectral emission. Its design is based upon a property exhibited in [19]-[21]: a chaotified nonlinear system presents many small independent chaotic attractors. The initial nonlinear system is chaotified using a simple sine function of the system state, as in [7], but with large amplitude. The feasibility and usefulness of this new and simple method is shown here with a numerical example, in a power factor correction (PFC) Boost Buck converter [24].

## 2. ANTICONTROL OF CHAOS

Consider a  $N$ -dimensional nonlinear system in the following general form

$$\begin{cases} \dot{x}_1 = \sum_{i=1}^N a_i x_i + \sum_{i=1}^N \sum_{j=1}^N b_{ij} x_i x_j + \sum_{i=1}^N c_i x_i^2 x_j + \delta \\ \dot{x}_2 = \sum_{i=1}^N m_i x_i + \sum_{i=1}^N \sum_{j=1}^N n_{ij} x_i x_j + \sum_{i=1}^N o_i x_i^2 x_j \\ \vdots \\ \dot{x}_N = \sum_{i=1}^N q_i x_i + \sum_{i=1}^N \sum_{j=1}^N r_{ij} x_i x_j + \sum_{i=1}^N s_i x_i^2 x_j \end{cases} \quad (1)$$

where  $a_i, b_{ij}, c_{ij}, m_i, n_{ij}, o_{ij}, q_i, r_{ij}, s_{ij}$  for  $i, j = 1, N$  are real parameters and  $x_i$  for  $i = 1, N$  are the state variables. In order to generate a chaotic behavior in this system, let us introduce a piecewise-binary characteristic of the feedback controller  $\delta$ , defined analytically as follows:

$$\delta = \begin{cases} 0, & v_r(t) < v_c(t) \\ 1, & v_r(t) \geq v_c(t) \end{cases} \quad (2)$$

where  $v_r(t)$  is a periodic function and  $v_c(t)$  the anticontrol state feedback. We propose to use the anticontrol with a piecewise-binary controller, hereafter called anticontrol switching piecewise-binary controller. The application of the anticontrol of chaos uses a nonlinear state feedback:

$$v_c(t) = c \cdot \sin[\omega \cdot x_1(t)] \quad (3)$$

We consider now a fast dynamics variation of  $\delta$  given by the anticontrol switching piecewise-binary controller  $\delta$  of (2). As Figure 1 presents, for each attractor starting from different initial conditions, the dynamical state space trajectory remains around the equilibrium point.

Figure 1. Example of chaotic attractors.

The application of the piecewise-binary controller  $\delta$  in continuous-time nonchaotic systems (1), outlines two very important properties. The first one is the generation of several independent periodic attractors. Recently, [21] demonstrated that the equidistant repartition of these attractors is in a precise zone (a controllable state space area) of a precise curve, which depends of the sine anticontrol feedback  $v_c(t)$  frequency. Then, the state space domains where the attractors are generated from different initial conditions were determined. Also, a mathematical formula giving the maximal attractors number in function of the controller piecewise-constant values has been deduced [21]. In this paper, we are interested by the second property: the size of the attractors. The design of this controller is based up on the property that chaotified nonlinear systems present many independent chaotic attractors of small dimensions: this is used to improve the EMC of PFC Boost-Buck converter by reducing spectral peaks.

### 3. THE BUCK CONVERTER

Figure 2 shows the diagram of a Buck converter that uses a pulse width modulated voltage loop [2]. The circuit has two states determined by the position of the switch  $S$ . When  $S$  is closed, the input voltage  $V_{in}$  provides energy to the load  $R_L$  as well as to the inductor  $L_L$ . When  $S$  is open, the inductor current  $i$ , who flows through diode  $D$ , transfers some of its stored energy to the load  $R_L$ . The anticontrol switching piecewise-binary control law together with a typically proportional (the constant  $a$ ) controller

$$v_c(t) = a \cdot [v(t) - V_{ref}] + c \cdot \sin[\omega \cdot v(t)] \quad (4)$$

is applied to the inverting input of the comparator  $A_1$ . The non-inverting input is connected to an independent voltage ramp generator  $v_r(t)$ :

$$v_r(t) = V_L + (V_U - V_L) \frac{t \bmod T}{T}. \quad (5)$$

The Buck converter is a second-order system since it has inductive and capacitive energy storage elements. The voltage  $v$  of the capacitor  $C$  and the inductance current  $i$  are chosen as state variables. This classical converter has been studied for many years, notably in [2], [3] assuming a regulated dc power supply input voltage. But usually, such is not the case in reality. The dc input voltage  $V_{in}(t) = E + e \cdot \sin(2\pi ft)$  will contain a ripple.

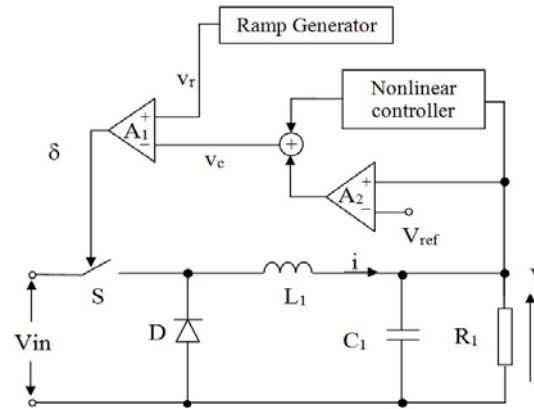

Figure 2. Buck converter with feedback anticontrol of chaos:  $L_1 = 10$  mH,  $C_1 = 33$   $\mu$ F,  $R_1 = 1.5$   $\Omega$ ,  $V_{ref} = 24$  V,  $a = 8$ ,  $V_U = 8.2$  V,  $V_L = 3.8$  V,  $E = 240$  V,  $e = 16$  V,  $f = 50$  Hz and  $T = 20$   $\mu$ s.

The model of the converter can be written as:

$$\begin{cases} \frac{dv}{dt} = \frac{1}{C} i(t) - \frac{1}{RC} v(t) \\ \frac{di}{dt} = -\frac{1}{L} v(t) + \frac{E + e \cdot \sin(2\pi ft)}{L} \delta(t) \end{cases} \quad (6)$$

Varying the values of parameters  $c$  and  $\omega$ , Figure 3 presents the maximum of the output voltage ripple in function of the anticontrol feedback parameters. This ripple falls to very small values for high  $c$  and  $\omega$  amplitudes. The low ripple area can then be identified. Every point  $(c, \omega)$  inside of this area is characterized by a small output voltage ripple and several chaotic attractors, dependent of the initial conditions (using (4) with large amplitude of  $c$ ). Figure 3 presents another area characterized by an important output voltage ripple and a unique attractor, independent of the initial conditions. We begin with a series of typical waveforms (the output voltage, the power spectrum and phase portrait of the state equation of the Buck converter Figure 4 – Figure 15) which have been obtained from computer simulations.

Figure 3. The maximum of the output voltage ripple in function of the anticontrol feedback parameters  $c$  and  $\omega$ .

The output voltage of this circuit, when the converter is governed by the control law of Eq. (4) with  $c=0$  is shown in Figure 4: it is periodic with a low frequency of 50Hz (the frequency of the input voltage  $V_{in}$ ). In this case we obtained a 10 mV ripple. A close-up view of the output voltage  $v(t)$  shows the high switching frequency of 50kHz.

Figure 5 represents the power spectrum of the output voltage  $v(t)$ . The spectrum has a peak at the switching frequency, with a magnitude of -80dB/Hz. Figure 6 shows the phase portrait which corresponds to the periodic orbit. For electromagnetic compatibility compliance reasons, let us try to reduce the peak value of the spectrum while maintaining a small ripple.

Figure 4. The periodic output voltage  $v(t)$  of the Buck converter with the control law of Eq. (4) for  $c=0$ .

Figure 5. Power spectrum of the output voltage  $v(t)$  with the control law of Eq. (4) for  $c=0$ .

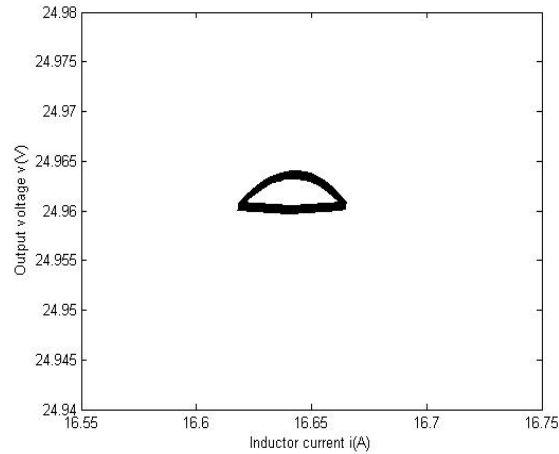

Figure 6. Phase portrait of the state equation of the Buck converter for  $c=0$ .

Let us suppose that  $c$  has a small amplitude as in [8] [10]. Unfortunately, the time-domain performance is worsened because the output voltage ripple has increased to 500 mV as in Figure 7. The small amplitude of the parameter  $c$  leads to the conclusion that, the efficiency of the DC-DC converter reduces, as in [11]. Figure 8 presents the power spectrum of the output voltage  $v(t)$ , for  $c = 5V$  and  $\omega = 100 \text{ rad/V}$ : the maximum of this spectrum is equal  $-64\text{dB/Hz}$ . The output voltage  $v(t)$  has a large variation attracted into an chaotic attractor as in Figure 9. Applying the anticontrol chaos (with small amplitude of  $c$ ) to switch-mode power supplies aggravates the time-domain performance, but also deteriorates the frequency-domain performance.

Figure 7. The output voltage  $v(t)$  of the Buck converter with the control law of Eq. (4) for  $c=5V$  and  $\omega=100 \text{ rad/V}$ .

Figure 8. Power spectrum of the output voltage  $v(t)$  with the control law of Eq. (4) for  $c=5V$  and  $\omega = 100$  rad/V.

Figure 9. Chaotic attractor phase portrait of the state equation of the Buck converter for  $c = 5V$  and  $\omega = 100$  rad/V.

We are interested in a large variation of the parameter  $c$ . Let us show that the  $c$  amplitude of the anticontrol of chaos state feedback  $v_c(t)$  has the key role to maintain a small ripple in the output and is able at the same time to achieve low spectral emission. Increasing the  $c$  amplitude decreases the output voltage ripple (see the 0.5 mV of Figure 10) and the maximum of the power spectrum decreases also (see the -120 dB/Hz of Figure 11). The reduction of the maximum of the power spectrum of  $v(t)$  can be achieved by increasing also the angular amplitude  $\omega$ . The dimension of the chaotic attractor decreases (Figure 12).

Figure 10. The output voltage  $v(t)$  of the Buck converter with the control law of Eq. (4) for  $c=150\text{V}$  and  $\omega=500\text{ rad/V}$ .

Figure 11. Power spectrum of the output voltage  $v(t)$  with the control law of Eq. (4) for  $c = 150\text{V}$  and  $\omega = 500\text{ rad/V}$ .

Figure 12. Chaotic attractor phase portrait of the state equation of the Buck converter for  $c = 150\text{V}$  and  $\omega = 500\text{ rad/V}$ .

Table 1 summarizes the ripple and the power spectrum of the output voltage  $v(t)$ , using different values of the parameter  $c$ . It shows that the power spectrum amplitude of the converter governed by a control law  $v_c(t)$  with small amplitude of  $c$  increases the power contained in the peaks harmonics of the output voltage and leads to a large ripple. The large values of  $c$  and  $\omega$  we propose ensure a good ripple and cause a spectacular decrease of the power spectrum amplitude.

Table 1. The performance of the Buck converter with different values of  $c$  and  $\omega$ .

$c$ (V)	$\omega$ (rad/V)	Ripple (mV)	Maximum of power spectrum (dB/Hz)
0	0	10	-80
5	100	500	-64
150	500	0.5	-120

Figure 13 presents several independent chaotic attractors reached from different initial conditions for small variations of  $c$ . In order to avoid the superposition of the attractors in a graphical state space representation, we represent them according to  $v(t)$  and  $c$  in Figure 13. Let us study their repartition in the state space in function of  $c$ . For small  $c$ , the Buck converter is characterized by a unique attractor. For a large  $c$ , the system presents several independent chaotic attractors, reached from many different initial conditions, as in Figure 14. Without any change of the Buck converter parameters, all the chaotic attractors are situated on the same curve depending on  $R$ . In order to avoid different regimes of operation (as Figure 14) and to make the Buck system converge to one attractor of interest (with the output voltage around  $V_{ref}$ ), starting from different initial conditions, the anticontrol switching piecewise-binary control law is used together with a classical PID controller. The simulation results are presented in Figure 15.

Figure 15. Independent chaotic attractors of the Buck using anticontrol switching piecewise-binary control law together with a classical PID controller.

#### 4. TWO-STAGE PFC POWER SUPPLIES

Power-factor-correction power supplies are required to provide high input power factor [12] and tight output voltage regulation. The objective of an active PFC is to make the input of the power supply look like a simple resistor: the PFC preregulator does this by programming the input current in response to the input voltage. Recently some nonlinear behaviors in the PFC boost converter have been reported [13] [14] [25] as fast-scale bifurcation [15-17] and slow-scale bifurcation [17] [18]. The above bifurcations are both observed at the switching frequency. The PFC converter is a more complicated system and an interesting case, because the input voltage is periodic with low frequency and the switching signal is periodic with high frequency.

The usual configuration takes a two-stage PFC dc/dc cascade structure, consisting of a PFC preregulator and a dc/dc converter. Both are designed to operate in continuous conducting mode. In this paper, we study by computer simulations the interaction between the PFC stage and the dc/dc Buck converter stage on the design of the anticontrol of chaos state feedback to achieve low spectral emission.

The boost converter circuit schematic used in the PFC is shown in Figure 16. The component values of the complete Simulink of the two-stage PFC power supply, with both the boost PFC preregulator and the Buck output regulator is presented in Appendix A. The feedback of the PFC Boost stage is necessary to program the input current to follow the input voltage waveform and must control both the input current and the PFC output voltage. To achieve near unity power factor the demanded current is in phase with the demanded voltage. The demanded voltage  $V_{PFCref}$  is compared to the capacitor voltage  $v_{outboost}$  and the error signal is filtered using a typical first-order low-pass filter (with the time constant  $T_v$ ) to remove any unwanted noise. The filtered error is fed to a conventional PI controller ( $P_2$  and  $P_2/T_c$  the constants) and the output is multiplied by the rectified input voltage times by a proportionality constant  $P_I$ .

The output of the multiplier is the current programming signal that has the shape of the input voltage. The PFC output voltage is controlled by changing the peak current mode control amplitude (as in Figure 17) of the current programming signal. The boost PFC preregulator typically gives a high output voltage (as in Figure 18) which is greater than the highest expected peak input voltage and provides very crude regulation. This way, a Buck converter is needed to step this voltage down to a useable level and to provide tight output regulation. In this part, the same Buck converter is used, with the same parameters as in the previous part.

The results concerning the maximum of the output voltage ripple in function of the anticontrol of chaos feedback parameters  $c$  and  $\omega$  for the complete two-stage PFC power supply are presented in Figure 19. This ripple falls to very small values for a wide domain of low  $\omega$  angular frequencies and for high  $c$  amplitudes. The low ripple area can then be identified for high  $c$  amplitudes. Every point ( $c$  and  $\omega$ ) inside of this area is characterized by a small output voltage ripple and several chaotic attractors, dependent of the initial conditions (with large amplitude of  $c$ ). Figure 19 also presents a grey area: every point inside of this area is characterized by an important output voltage ripple and a unique attractor, independent of the initial conditions.

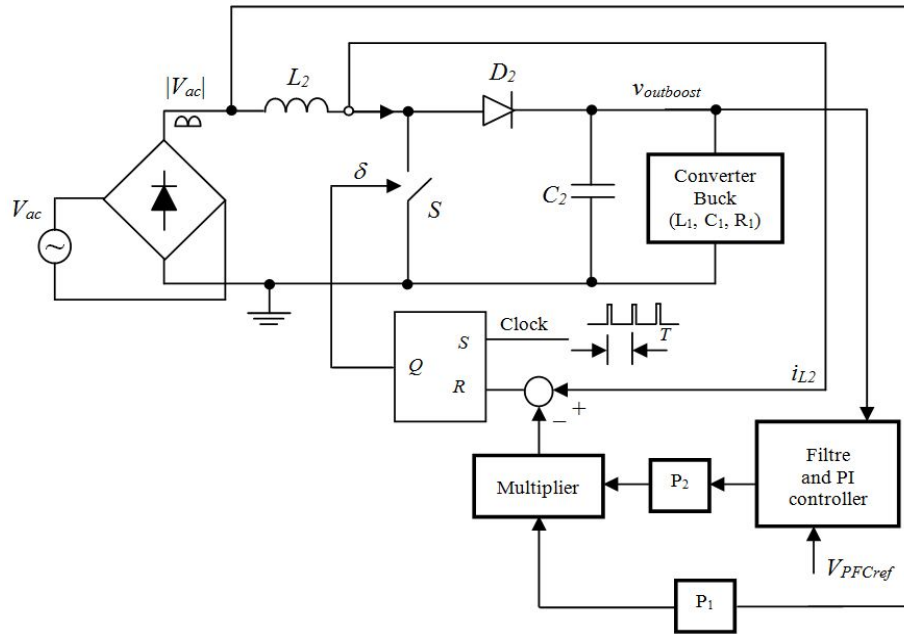

Figure 16. The PFC Buck-Boost power supply converter.

Figure 17. Inductor current  $i_{L2}$  from PFC Boost stage.

Figure 18. The output voltage  $v_{outboost}$  of the Boost PFC preregulator.

Figure 19. The maximum of the output voltage ripple  $v(t)$  in function of the anticontrol feedback parameters  $c$  and  $\omega$ , of the complete two-stage PFC power supply.

For few particular values (the same choice of parameters as for the Buck converter) of the anticontrol feedback parameters  $c$  and  $\omega$  of the complete two-stage PFC power supply, we present the output voltage, the power spectrum and phase portrait (Figure 20 – Figure 28).

Figure 20 shows the waveform of the output voltage  $v(t)$  of the complete two-stage PFC power supply with the control law of Eq. (4) for  $c = 0$ , where it can be seen a ripple of smaller than 10 mV. The power spectrum of  $v(t)$  is mainly composed of the fundamental frequency (a -90 dB/Hz sharp peak at 50 kHz) and its harmonics, as presented in Figure 21. Figure 22 shows the phase portrait of  $(i, v)$ .

Figure 23 also presents that the parameter  $c$  has a strong influence on the output voltage ripple. For example, while  $c$  changes from 0 to 5 V, there is an increase of the ripple up to 500 mV. The power spectrum of  $v(t)$  of the complete two-stage PFC power supply is shown in Figure 24. It is known that the amplitude at the clock frequency (50 kHz) is the main source of EMI due to power converters. We observe a 5 dB/Hz increase of this amplitude for the output voltage  $v(t)$ . Consequently, Figure 25 presents an increasing phase portrait dimension of the chaotic attractor.

If  $c$  amplitude of the anticontrol of chaos state feedback  $v_c(t)$  is increased even more, then the maximum of the power spectrum decreases, as shown in Figure 27. The non-periodicity of the power spectrum of  $v(t)$  indicates the presence of chaos. The whole frequency range is continuously spanned. The dimension of the chaotic attractor (Figure 28) in the phase portrait also decreases.

We report our measurements in Table II and summarize the ripple and power spectrum of  $v(t)$ , using the same particular values of the anticontrol feedback parameters  $c$  and  $\omega$  of the complete two-stage PFC power supply as for the Buck converter. The nonlinear feedback controller  $v_c(t)$  proposed here with large amplitudes of  $c$  maintains a small ripple in the output and is able at the same time to achieve low spectral emissions. This demonstrates that anticontrol of chaos improves power supply EMC.

Similar to the analysis of the Buck converter, the anticontrol of chaos state feedback  $v_c(t)$  still achieves low spectral emission and maintains a small ripple even if this one is used as load for the PFC Boost converter. In other words, we may conjecture from the above results that anticontrol switching piecewise-binary control law  $v_c(t)$  presents a typical characteristic: low spectral emissions.

Table 2. The performance of the PFC Buck-Boost converter with different values of  $c$  and  $\omega$ .

$c$ (V)	$\omega$ (rad/V)	Ripple (mV)	Maximum of power spectrum (dB/Hz)
0	0	10	-90
5	100	550	-85
150	500	0.5	-170

$$T_v = 4 \text{ ms}, T_c = 1/70 \text{ s}, P_2 = 1/60, P_l = 0.08, V_{pFCref} = 240\text{V}, T = 20 \text{ }\mu\text{s}.$$

## 5. CONCLUSION

We propose a feedback control to the complete two-stage PFC power supply in order to demonstrate that chaos improves power supplies EMC without any other feedback. To confirm the efficiency of this new method, a comparison with the anticontrol method is included. Indeed, the application of the classical method of chaos anticontrol to these systems leads the output voltage to have an exaggerated output voltage ripple and an undesirable spectrum, whereas these problems are solved with ours. The new controller proposed in this paper improves the time-domain (ripple) performance and the frequency-domain (spectral) performance.

## BIOGRAPHIES OF AUTHORS

**Marcelle Merhy** was born in Lebanon in 1986. She graduated from the lebanese university of Beyrouth (Hadath-Liban) in 2007. She had her Master2 in Electromagnetic Compatibility from the University of Blaise Pascal (Clermand-Ferrand) in 2008.

She received the Ph.D in 2012 on the nonlinear phenomena in electrical engineering and applications to power electronics in Engineering School in Electronics and Computer Science (ESEO).

**Cristina Morel** received the M.Sc. degree in automatic control in 1992 from the Polytechnical University of Cluj-Napoca and the Ph.D in 2005, from the University of Angers.

After teaching at the University of Angers, she is currently an associate professor in the Engineering School in Electronics and Computer Science, where she has been working since 2006. Her current research interests include the nonlinear phenomena in electrical engineering and applications to power electronics.

**Eric Chauveau** was born in France in 1972. He graduated from ESAIGELEC, Saint-Nazaire, an engineering school in electrical engineering and studied at the University of Nantes for his thesis. He obtained his Ph.D in 2001 for his work on coupled magnetic and thermal modeling of induction machines.

After teaching at the University of Nantes, he is currently at ESEO, Angers, an engineering school in electronics and computer science. His specialty is power electronics and electrical machines but he also gives courses on analog electronics, sensors and automation. His research interests include electrical energy conversion using power electronics associated with very innovative control solutions, for the field of sustainable energy.

**Mohamed Machmoum** was born in Casablanca, Morocco, on November 29, 1961. He received the Diplo. Engineering Degree in 1984 from the “Institut Supérieur Industriel of Liège”, Belgium, the Ph.D. degree from the “Institut National Polytechnique of Lorraine (INPL)”, France, in 1989, all in electrical engineering. In 1991 he joined “l’Ecole Polytechnique de l’Université de Nantes” as a Maître de Conférence. Since September 2005 he is a Professor at “Ecole Polytechnique de l’Université de Nantes” and responsible of “Power Quality and Renewable Energy” Group. His main area of interest includes power electronics, power quality, wind or tidal energy conversion systems and Power Line Communication. He is actually the head of IREENA Laboratory, Site of Saint Nazaire.
